

The Veterans Health Administrations Treatment of PTSD and Traumatic Brain Injury Among Recent Combat Veterans

More than 2 million service members have deployed in support of overseas contingency operations (OCO) in Iraq and Afghanistan since October 2001. Two combat-related conditions that affect some OCO veterans and that have generated widespread concern among policymakers are post-traumatic stress disorder (PTSD), an anxiety disorder induced by exposure to a traumatic event, such as witnessing injury or death) and traumatic brain injury (TBI, which is caused by sudden trauma to the head and is commonly sustained by service members exposed to explosions). In a study requested by the Ranking Member of the House Committee on Veterans Affairs, CBO analyzes VHA's care of OCO patients diagnosed with PTSD or TBI and compares the reported rates of occurrence of those conditions within VHA with estimates of the prevalence of those conditions in the broader population of service members who have deployed to recent overseas contingency operations. The study also examines the costs that VHA has incurred in treating patients diagnosed with PTSD and TBI.
